Many prior art signal processing and conversion circuits have been provided. For example, an audio signal produced by a sound source can be amplified by an amplifier, transformed by a digital-to-analog (D/A) converter, and converted back into an analog signal by an A/D converter. Some applications require sampling the incoming signal at a sampling frequency that is higher than that of the original signal. Thus, a digital-to-digital (D/D) converter may be used to convert the incoming digital signal into a stream of samples taken at a higher sampling rate. The resulting stream of samples may then be processed or processed further to reduce noise and other artifacts in the signal. In one example, audio signals are input to an audio interface that provides interface functionality with respect to processing such audio signals. The audio interface performs any necessary amplification, mixing, or filtering of the audio signal. The audio interface then outputs an analog audio signal to a D/A converter that converts the analog audio signal to a digital signal. The digital signal can be converted to analog by an A/D converter, which produces
