Saturday, May 26, 2017 Sawyer Farney: a Democrat's Democrat

It was the summer of 1968 and the Democratic Presidential campaign was on the cusp of an absolutely decisive victory. No other candidate had been nominated in the primary and there was no election looming in November. The symbolism was undeniable. The Party of FDR and Kennedy, the Party of the New Deal and New Frontier was ready to be crowned king. Even after the Kennedy campaign folded, even after the great defeat in 1964, the belief was that the President was a ghost, that the people had rejected the Democratic Party in the White House. The next time that a Democrat won, it was not going to be under LBJ's leadership. It was going to be under another from his tradition: Massachusetts Senator Edward Kennedy. But there was one problem. Those Kennedy

---

supporters held firm to their belief. They believed, after all, that they supported the Party of Franklin Roosevelt and John Kennedy and the small New Deal coalition, the common man. But they were wrong and they had to realize that they were wrong. They needed to see that they were wrong. And so they threw the party leadership in 1964 under the bus. And it wasn't Barry Goldwater who was 'sold out.' It

---

can therefore be released later (a negative effect). The interesting result in the alcohol condition was that the reduction in response rate was not cancelled. After the alcohol, the responding increased to levels approaching those seen before alcohol. This is most likely due to the continued presence of dopamine in the synapse, thus releasing enough dopamine to maintain the increase in rate. But, it is also possible that dopamine levels have been increased somewhat by the alcohol, and, in that state, the dopamine continues to be released and cause an increase in rate. Clemens and Hanser (1991) also found that an acute alcohol dose increases the number of dopamine vesicles that are available to release dopamine. They suggested that this could allow alcohol to suppress depression by augmenting the release of dopamine. Anti-depressants are capable of blocking the release of dopamine in the VTA and other areas of

---

the brain. In one type of depression, it has been suggested that more vesicles may be stored in the neuron, which could then be released more readily (Gaya, 1991).

Current research indicates that the VTA is involved in several significant aspects of reward and reinforcement. An increase in the number of dopamine vesicles in the VTA is a possible mechanism for greater reward. Furthermore, the VTA is thought to be involved in both learning and memory (Ragozzino, 1991). Antidepressants may work by exerting changes in the VTA.

However, a number of clinical trials have failed to prove that antidepressants work as well for
