Front and Back.In the oil field industry, wellbores are drilled to locate and produce hydrocarbon deposits from subterranean hydrocarbon-bearing formations. The wellbore is typically drilled in segments using a drill string. As is known in the art, a drill string includes a tubular member having a drill bit secured to the distal end thereof. To drill the wellbore, a rotary drill bit is advanced downwardly at a lower end of the drill string. As the drill bit progresses downwardly through the wellbore, it can be used to form a new path for drilling fluid, which is commonly referred to as "mud." The drilling fluid flows through the drill string and exits through the drill bit. The drilling fluid lubricates and cools the drill bit, and then flows back to the surface through the annular path defined between the drill string and wellbore to lubricate and cool the drilling equipment. The flow of drilling fluid through the wellbore is also used to remove formation cuttings from the wellbore. The drilling fluid may be a water base fluid or an oil base fluid. In addition, the drilling fluid may contain weighting agents, stabilizing agents, and the like. During the drilling process, to increase the ability to select the proper path for the drilling operation, various measurement tools are utilized. For example, a steerable downhole drilling motor may be used in combination with a downhole measuring device to steer the drilling device through the wellbore so that the wellbore will be steered to pass a desired measurement location. The downhole tool may measure wellbore parameters such as direction, inclination, wellbore pressure, and the like. For example, a sensor may be used to measure the direction of the drilling device while a device 6d1f23a050
