Solucionario De Geankoplis Procesos De Transporte Y Operaciones 21

I expect the result in the format above. A: This can be achieved by using stack/recursion. The idea is to fetch all the needed information for one entry and eventually store it in a list. This way you don't need to fetch information for the entire table but only for the current entry. With this you can store your data in a table and at the end concatenate them to a string (I am using a list of lists here as you didn't specify which data structure you want to use). def extract_list(table, ref_num): """ ;param table: pandas dataframe ;param ref_num: unique number of each entry :return: list of dataframes """ all_data = [] for index, row in table.iterrows(): # for each row in the table just retrieve the values # in a dictionary: dict_row = {i: j for i, j in zip(table['name'], table['value'].loc[row])} # now append all the needed values to a list all_data.append([ref_num, dict_row]) return all_data def print_data(data): """ ;param data: list of dataframes :return: """ print("Data: {}".format(data)) list_1 = [list_0, list_0, list_0] print("list_0") print("list_1") # extract all dataframes related to the first entry all_data = extract_list(df, 1) # print each list print("list_0") print("list_1") print("list_0") print("list_1") # now concatenate them to a single list all_data.append(list_0) all_data.append(list_1) print("list_0") print("list_1") print("list_0 c6a93da74d")
